

Global HPCC Benchmarks in Chapel:
STREAM Triad, Random Access, and FFT
(Revision 1.1 — HPCC BOF, SC06)

Bradford L. Chamberlain
Mary Beth Hribar

Steven J. Deitz
Wayne A. Wong

The first two lines define a domain and array used to represent the distributed table, T , that is randomly accessed

values are required in certain language contexts, such as when specifying a scalar type's bit-width or an array's

`computeProblemSize()` defined in the *HPCCProblemSize* module. This routine takes as its arguments the element type being stored and the number of arrays to be allocated and returns the problem size that will fill the appropriate fraction of system memory as an

The syntax for specifying a domain's definition is as follows:

```
domain [ ( <domain-args> ) ] [
```

a case this simple, even a modest compiler ought be able to eliminate the dynamic bounds check without any trouble.

```
}  
}
```

The body of `printConfiguration()` is guarded by a conditional statement whose test checks the value of the `config` const *printParams*. Conditionals in Chapel are similar to those in other modern languages. The first statement of the conditional calls a helper routine defined in the *HPCCProblemSizes* module which prints out some information about the problem size, taking in

This routine starts by constructing an instance of the *RandomStream* class which is defined in Chapel's standard *Random*

Configuration Variables, Default Arguments, Call-by-Argument Name, and Casts

```
forall block in subBlocks(UpdateSpace) do
  for r in RASStream(block.numIndices, block.low) do
    T(r & indexMask) ^= r;
```

This loop is an example of expressing parallelism in a simple, architecturally-neutral way, as alluded to in Section 3. Our goal is to create parallel work such that each locale has an appropriate number of threads, each performing a fraction of the locale's random updates. To this end, we create a parallel outer loop to describe the parallelism across the machine resources and a serial inner loop to express the updates owned by that resource.

that it is an array (due to the square brackets) but with no element type specified. This requires that the argument

An Explicit Module Declaration In all of our previous examples, we have defined modules that are not used by any other modules, and therefore have relied on the convenience of having the compiler generate a module name from the filename. For the *RARandomStream* module, we want to use it from other modules and would also like the option of creating several implementations in different files, so we scope the code and name the module as follows in

to be a *randType*

The final new concept is the use of a type cast to coerce a *tuple*

Locale Types and Variables

updates to the global table one element at a time, requiring a lot of fine-grain communication. For architectures that

At one end of the spectrum, even on a parallel machine with a flat shared memory like the Cray MTA, the clean expression of the computation as given here is unlikely to perform optimally. In Appendix C.2, we provide an alternate Chapel implementation of FFT that is based on last year's HPCC submission for the MTA2 [16]. In that implementation, several specialized versions of the inner loops were created in order to maximize outer-loop parallelism, take advantage of twiddle values with zero components and tune for the MTA's characteristics. While we might hope that our more straightforward implementation of the benchmark would come close to achieving the

In conclusion, it is worth noting that while these benchmarks have demonstrated many of Chapel's productivity features for global-view programming and software engineering, they remain rather restricted in terms of the parallel

C.2 Chapel Version of HPCC'05 1D radix-4 FFT for the MTA

In this section, we provide an alternate Chapel implementation of FFT, based on last year's HPC Challenge implementation for the Cray MTA [16]. This version of the code is provided to suggest some of the transformations that an aggressive performance-minded programmer might utilize to best take advantage of architectural characteristics.

```

58     if (i <= n/2) then
59         cftmd1(span, Z, Twiddlees);
60     else
61         cftmd2(span, Z, Twiddlees);
62     span *= radi x;
63 }

65 if (radi x*span == Z.numElements) then
66     forall j in [0..span) do
67         butterfly(1.0, 1.0, 1.0, Z[j..j+3*span by span]);
68 else
69     forall j in [0..span) {
70         const a = Z(j),
71               b = Z(j+span);
72         Z(j)    = a + b;
73         Z(j+span) = a - b;
74     }
75 }

78 def printConfiguration() {
